

Residuary drag estimation for a slender monohull

Jean-François Masset – July 2019

[jfcasset@outlook.fr](mailto:jfcmasset@outlook.fr)

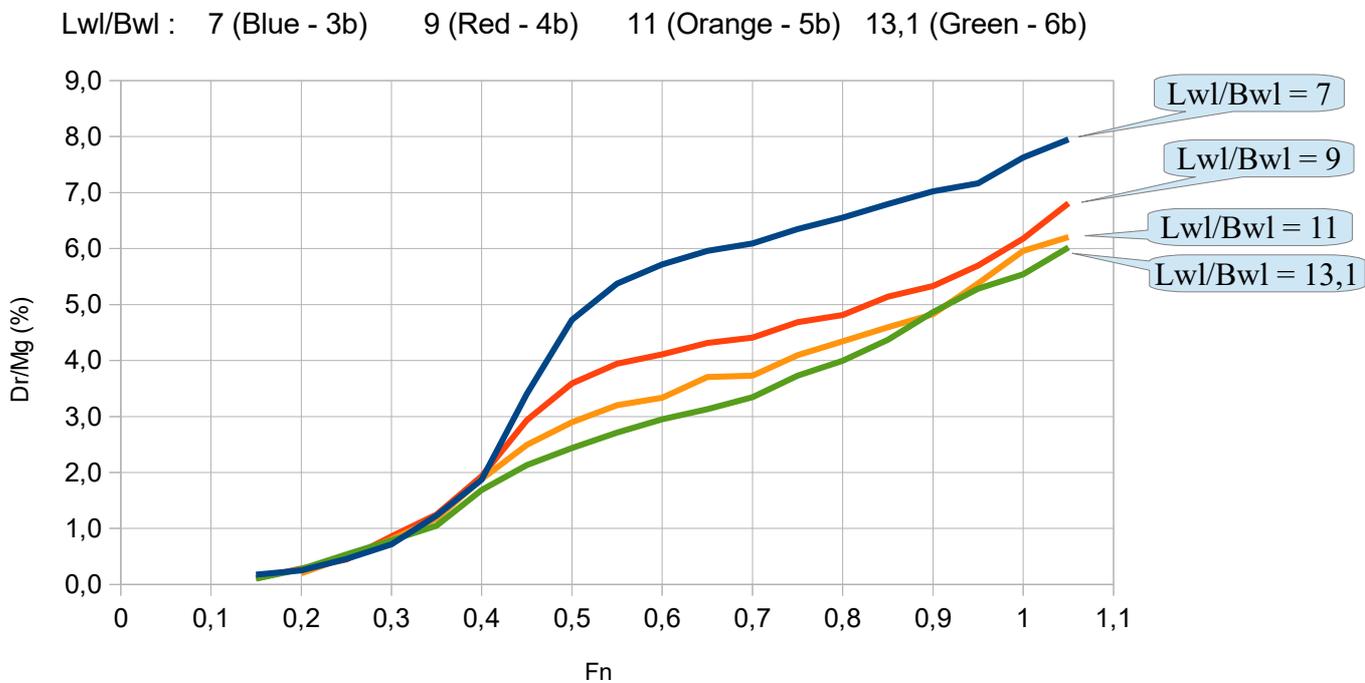

Abstract :

From the towing tank tests of a serie of slender monohull models (Reference and detailed analysis in page 2 and followings), sharing the same block coefficient ($C_b \sim 0,4$), one can propose this evaluation of the residuary drag component D_r in function of the ratios Lwl/Bwl and Bwl/Tc :

$$D_r/Mg (\%) = \text{Function} (Fn, Lwl/Bwl, \text{when } Bwl/Tc = 2) * \text{Correction (when } Bwl/Tc \neq 2)$$

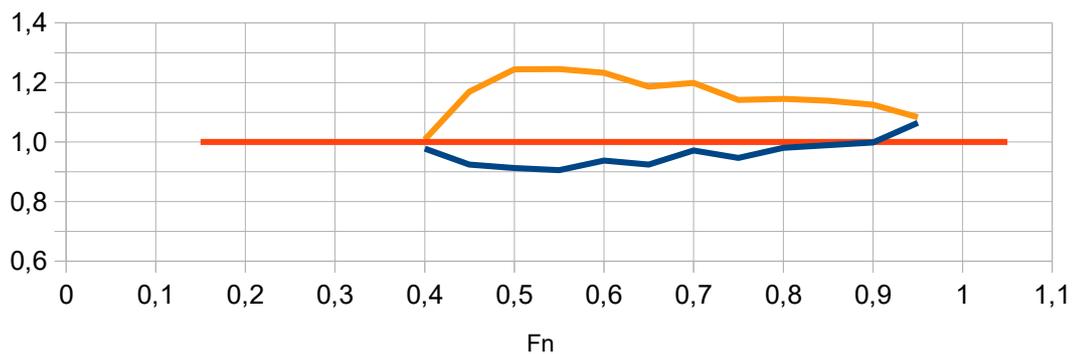

with : D_r : residuary drag ; Mg : weight of the monohull ; Fn : Froude number (based on Lwl)
 Lwl : length waterline ; Bwl : beam waterline ; Tc : hull draft

Residuary drag D_r - Monohull C_b 0,397 Bwl/Tc 2,0

Correction factor due to Bwl/Tc

Bwl/Tc : Blue (2,5) Red (2,0) Orange (1,5)

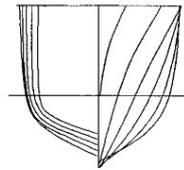

Detailed analysis

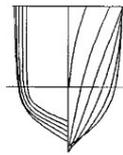

The residuary drag of a slender monohull with dimensionless parameters is proposed and discussed, on the basis of a series of models tested in the University Southampton towing tank and reported here below by A.F Molland / University of Southampton and Pat Couser / Bentley systems in January 1994 :

https://www.researchgate.net/publication/284260790_Resistance_experiments_on_a_systematic_series_of_high_speed_displacement_catamaran_forms_Variation_of_length-displacement_ratio_and_breadth-draught_ratio

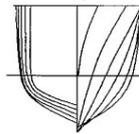

The tested models :

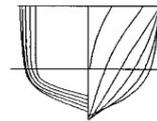

Model: 3b

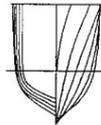

Model: 4a

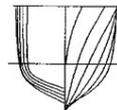

Model: 4b

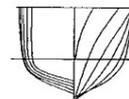

Model: 4c

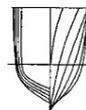

Model: 5a

Model: 5b

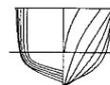

Model: 5c

Model: 6a

Model: 6b

Model: 6c

Model	L (m)	L/B	B/T	L/D ^{1/3}	C _b	C _p	C _m	Sw (m ²)	LCB (%Lwl)	>> D(m ³)	>> D (kg)
3b	1,6	7,0	2,0	6,27	0,397	0,693	0,565	0,434	-6,4	0,016617	16,62
4a	1,6	10,4	1,5	7,40	0,397	0,693	0,565	0,348	-6,4	0,010108	10,11
4b	1,6	9,0	2,0	7,41	0,397	0,693	0,565	0,338	-6,4	0,010067	10,07
4c	1,6	8,0	2,5	7,39	0,397	0,693	0,565	0,34	-6,4	0,010149	10,15
5a	1,6	12,8	1,5	8,51	0,397	0,693	0,565	0,282	-6,4	0,006646	6,65
5b	1,6	11,0	2,0	8,50	0,397	0,693	0,565	0,276	-6,4	0,006670	6,67
5c	1,6	9,0	2,5	8,49	0,397	0,693	0,565	0,277	-6,4	0,006693	6,69
6a	1,6	15,1	1,5	9,50	0,397	0,693	0,565	0,24	-6,4	0,004777	4,78
6b	1,6	13,1	2,0	9,50	0,397	0,693	0,565	0,233	-6,4	0,004777	4,78
6c	1,6	11,7	2,5	9,50	0,397	0,693	0,565	0,234	-6,4	0,004777	4,78

In the paper in reference the residuary drag of each slender monohull of the series is deduced from the tests and given in Figures 32a, b, c and d , through the resistance coefficient C_r , applied to $\frac{1}{2} \rho A u^2$, in function of Froude F_n . As A (the static wetted surface), u (the speed, known from the Froude number and the length L) and the model mass M (known from $L/D^{1/3}$ and $M = D \rho$), it is possible to convert these curves in the more appropriated adimensional form for such residuary (mostly wave) drag D_r , i.e. D_r/Mg (%) in function of F_n , so showing its independence to Reynolds.

Another point is the parameters used to graduated the various curves in the paper, in apparence they are 3 : Lwl/Bwl , Bwl/Tc , $Lwl/D^{1/3}$. But actually, all the models sharing the same block coefficient C_b (= 0,397), when 2 parameters are given, e.g. Lwl/Bwl and Bwl/Tc , the third one $Lwl/D^{1/3}$ is fixed through :

$$Lwl/D^{1/3} = [(Bwl/Tc)/C_b]^{1/3} (Lwl/Bwl)^{2/3}$$

So the curves presentation can be graduated stating that C_b is common (0,397) and using Lwl/Bwl or Bwl/Tc for the curves graduation.

Lwl/Bwl influence

At first, to demonstrate the approach, here is the Fig.32a of the paper (Residuary drag D_r of the models 3b, 4b, 5b, 6b at constant $Bwl/Tc = 2,0$) and its conversion in curves D_r/Mg (%) in function of F_n :

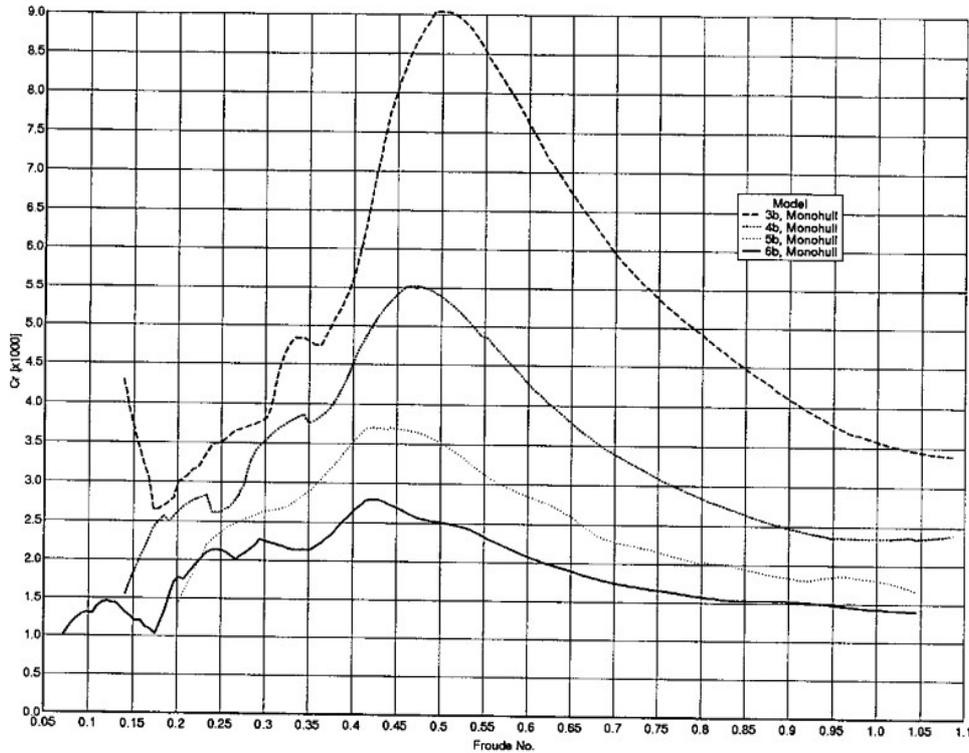

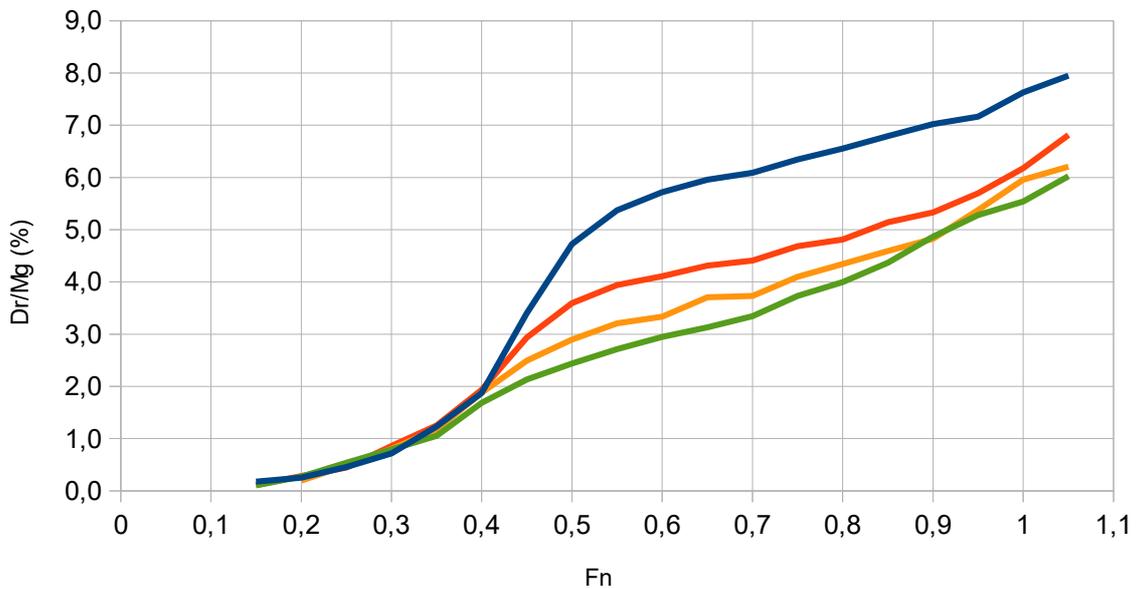

Fig 32a. Residuary Resistance: Models: 3b,4b,5b,6b (Monohull)

Residuary drag D_r - Monohull C_b 0,397 Bwl/Tc 2,0

Lwl/Bwl : 7 (Blue - 3b) 9 (Red - 4b) 11 (Orange - 5b) 13,1 (Green - 6b)

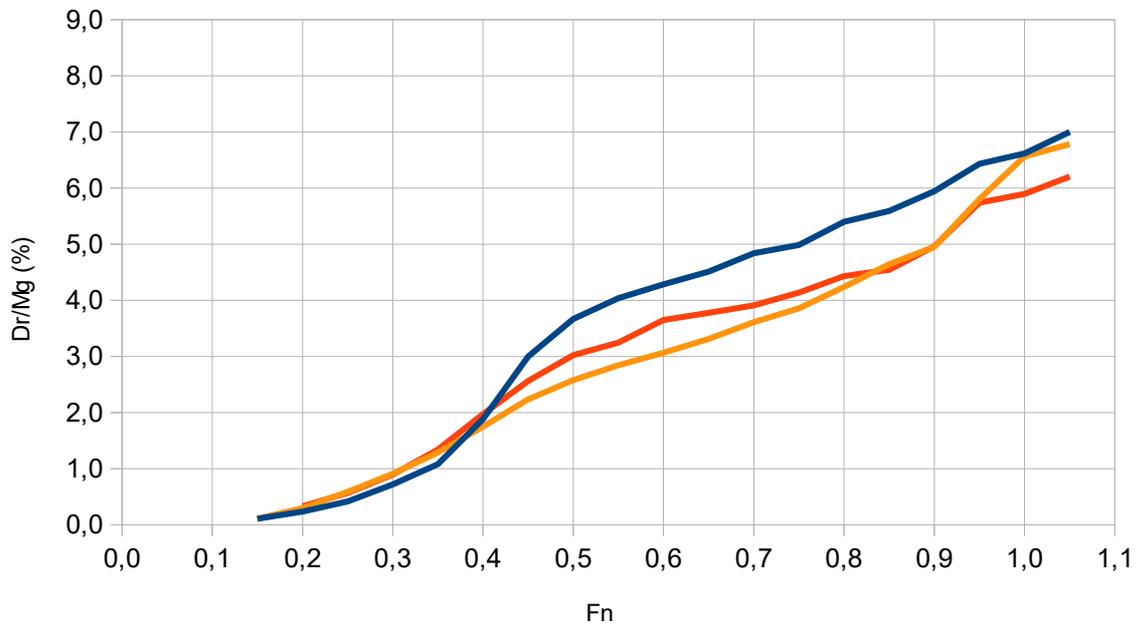

>>> One can see how different the curves appear and the conclusions that can be drawn

Results with models 4c, 5c , 6c , sharing $C_b = 0,397$ and $Bwl/Tc = 2,5$:
(built from Fig. 32b, 32c and 32d of the paper)

Residuary Drag D_r - Monohull $C_b 0,397$ $Bwl/Tc 2,5$

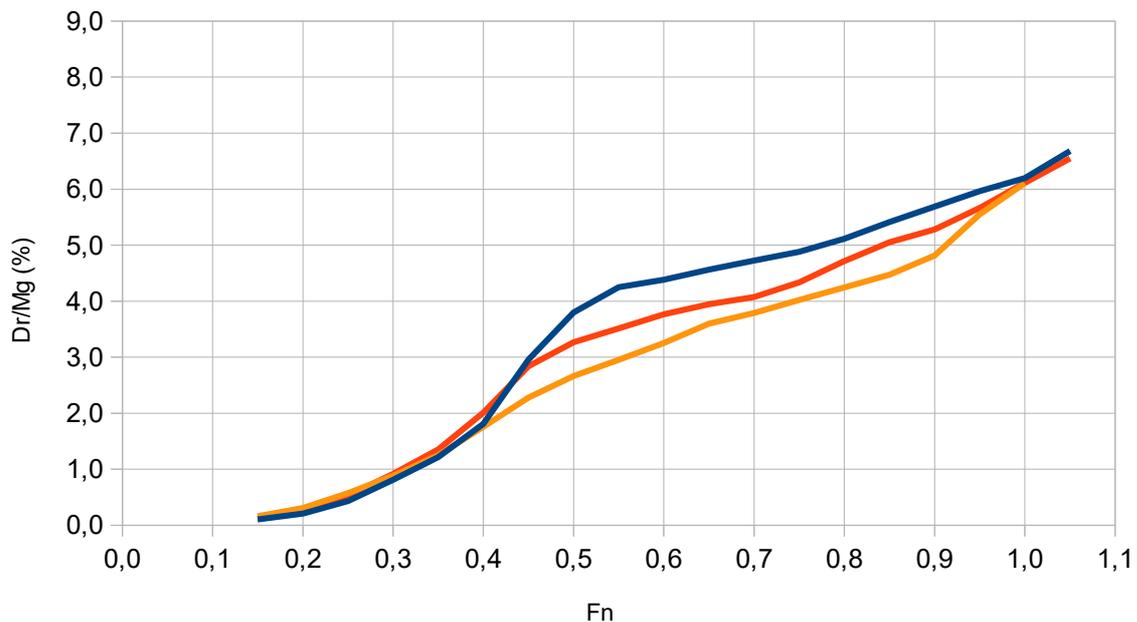

Lwl/Bwl : 8 (Blue) 9 (Red) 11,7 (Orange)

Results with models 4a, 5a , 6a , sharing $C_b = 0,397$ and $Bwl/Tc = 1,5$:
(built from Fig. 32b, 32c and 32d of the paper)

Residuary drag D_r - Monohull $C_b 0,397$ $Bwl/Tc 1,5$

Lwl/Bwl : 10,4 (Blue) 12,8 (Red) 15,1 (Orange)

Comments on these 3 curves for the 3 different Bwl/Tc :

- For Froude $< 0,15$, D_r is negligible
- For Froude $0,15$ to $0,40$: no clear difference due to the ratio Lwl/Bwl
- For Froude $0,40$ to $0,95$: there is a significant graduation of the drag force in the expected order, i.e. the residuary drag decreases when the Lwl/Bwl ratio increases.
- At Froude $0,95$ to $1,05$ the curves tends to converge to the same drag values.

>>> it seems relevant to aim a $Lwl/Bwl > 9$ at least to moderate the residuary drag component, an usual recommendation for catamaran hulls.

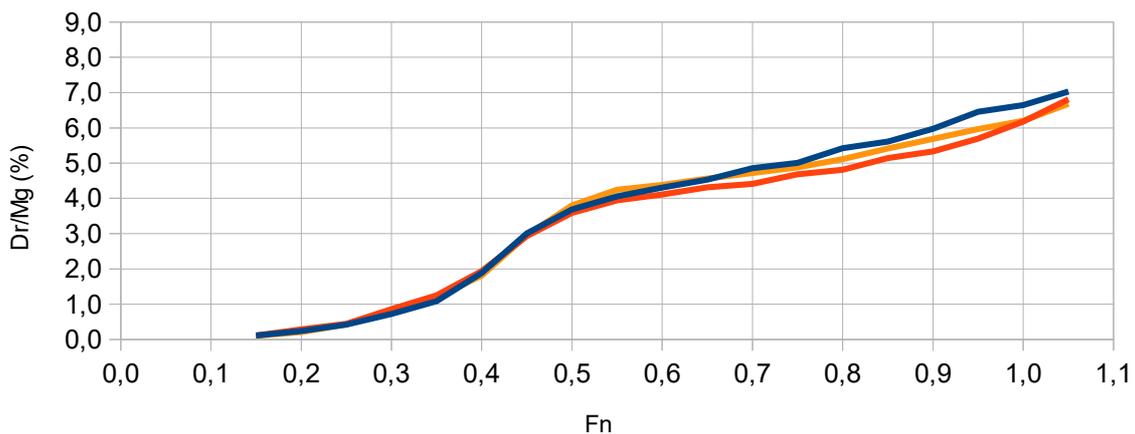

Bwl/Tc influence

To show the influence of Bwl/Tc , the paper propose the Fig. 32b, 32c and 32d but they are not at same Lwl/Bwl which prevent to draw consistent conclusions on the Bwl/Tc influence >>>

Converted results directly from Fig. 32b with models 4a, 4b , 4c :

Residuary drag D_r - Monohull Cb 0,397

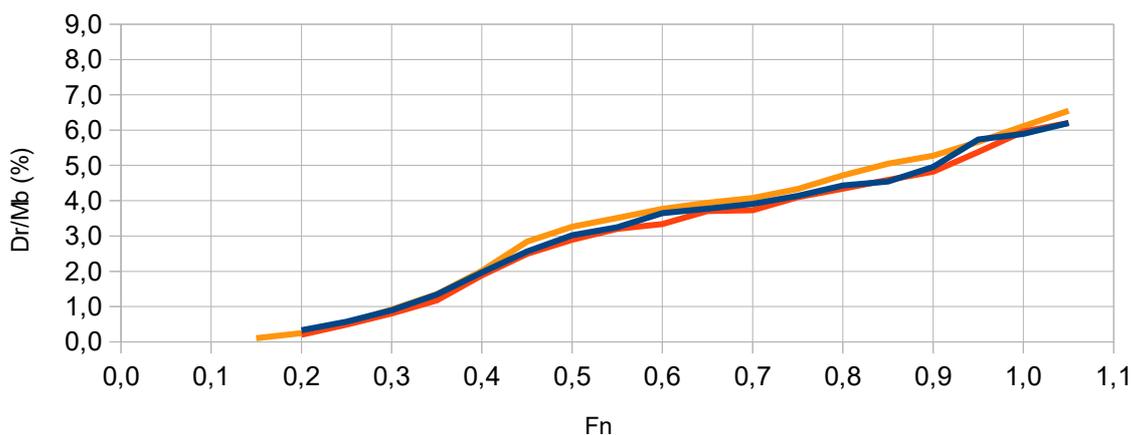

Lwl/Bwl : 8 (Blue) 9 (Red) 10,4 (Orange)
 Bwl/Tc : 2,5 (Blue) 2,0 (Red) 1,5 (Orange)

Converted results directly from Fig. 32c with models 5a, 5b , 5c :

Residuary drag D_r - Monohull Cb 0,397

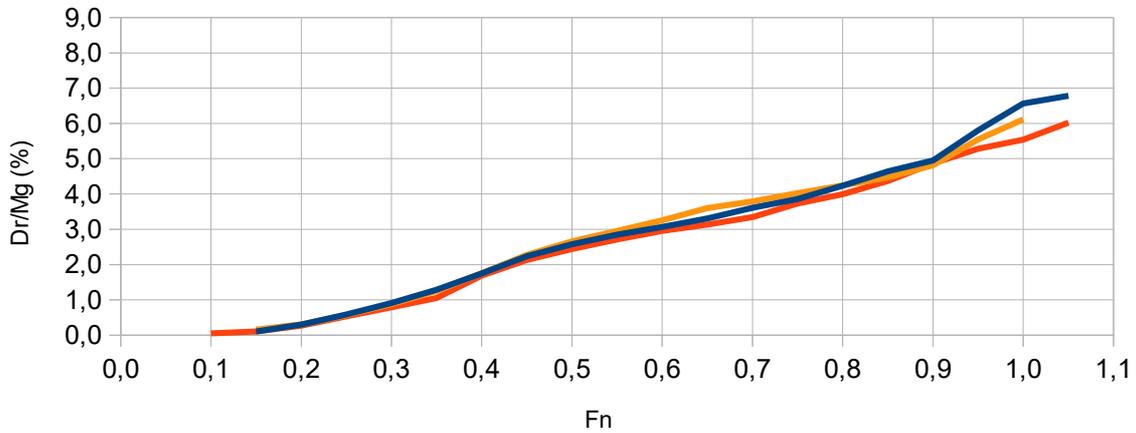

Lwl/Bwl : 9 (Blue) 11 (Red) 12,8 (Orange)
 Bwl/Tc : 2,5 (Blue) 2,0 (Red) 1,5 (Orange)

Converted results directly from Fig. 32c with models 6a, 6b , 6c :

Residuary drag Dr - Monohull Cb 0,397

Lwl/Bwl : 11,7 (Blue) 13,1 (Red) 15,1 (Orange)
 Bwl/Tc : 2,5 (Blue) 2,0 (Red) 1,5 (Orange)

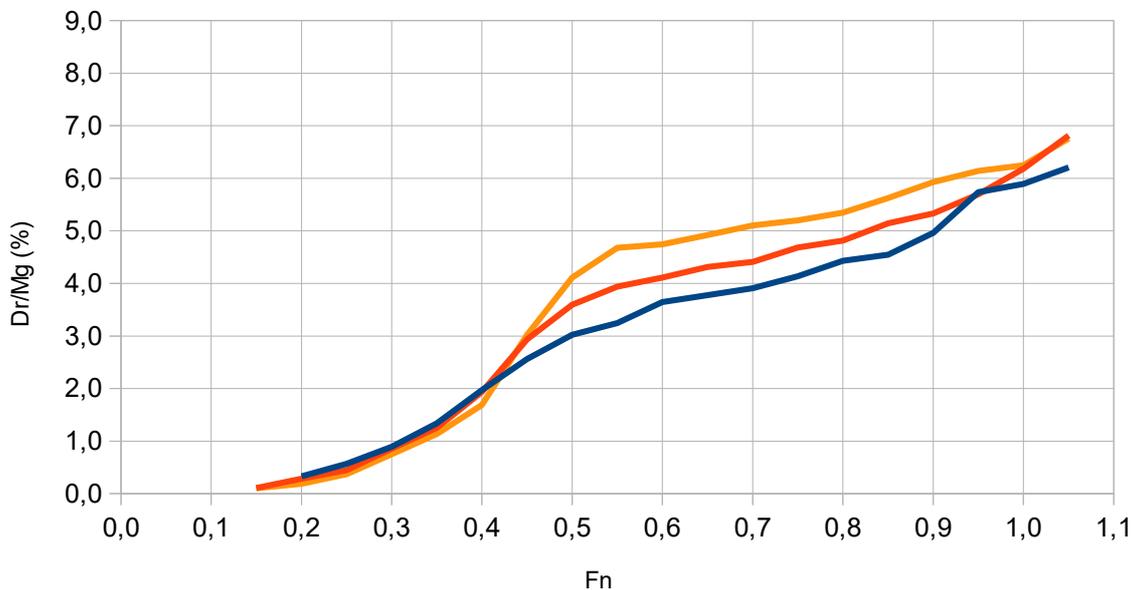

Comments : no apparent difference but as expected, we cannot draw conclusions on Bwl/tc influence from these figures as the Lwl/Bwl are also variable : e.g. on the figure above how to compare Bwl/Tc 2,5 and 1,5 when associated with Lwl/Bwl with respectively 11,7 and 15,1 ?

>>> **So another presentation of the same results is necessary with constant Lwl/Bwl**, and it is proposed through some linear interpolation computed from the available data, as close as possible to the real results in order to not loose in consistence and accuracy. That leads to the figures here below, done with 5 different Lwl/Bwl to be sure of the method stability

Bwl/Tc influence at Lwl/Bwl = 9

Residuary drag Dr - Monohull Cb 0,397 Lwl/Bwl 9

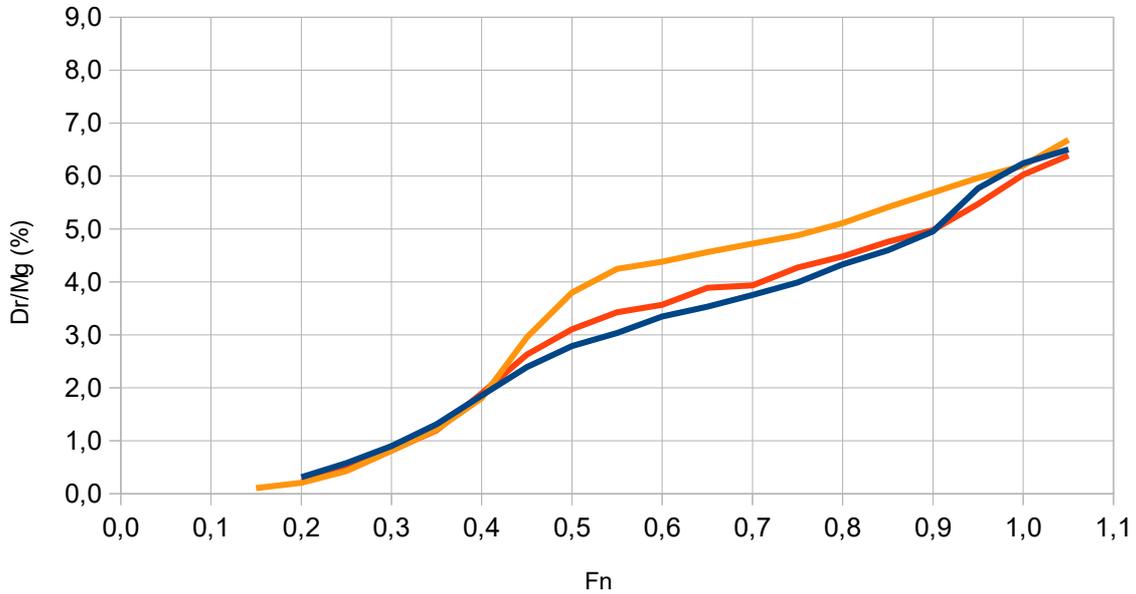

Bwl/Tc 2,5 (Blue) 2,0 (Red) 1,5 (Orange, from interpolation)

Bwl/Tc influence at Lwl/Bwl = 10,4

Residuary drag D_r - Monohull C_b 0,397 L_{wl}/B_{wl} 10,4

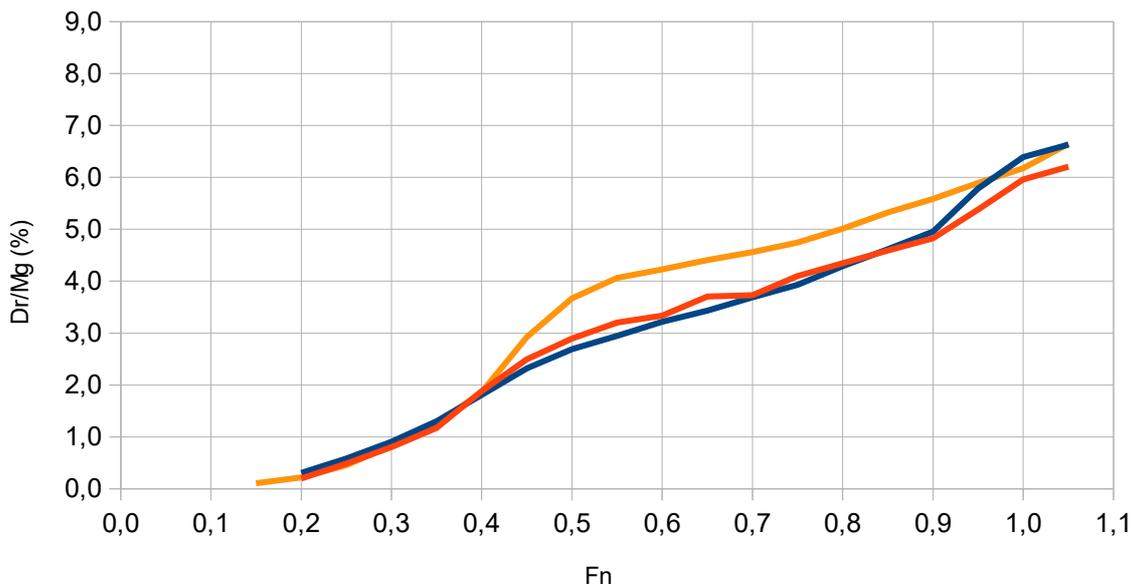

B_{wl}/T_c 2,5 (Blue, from interpolation) 2,0 (Red, from interpolation) 1,5 (Orange)

Bwl/Tc influence at Lwl/Bwl = 11

Residuary drag D_r - Monohull C_b 0,397 L_{wl}/B_{wl} 11

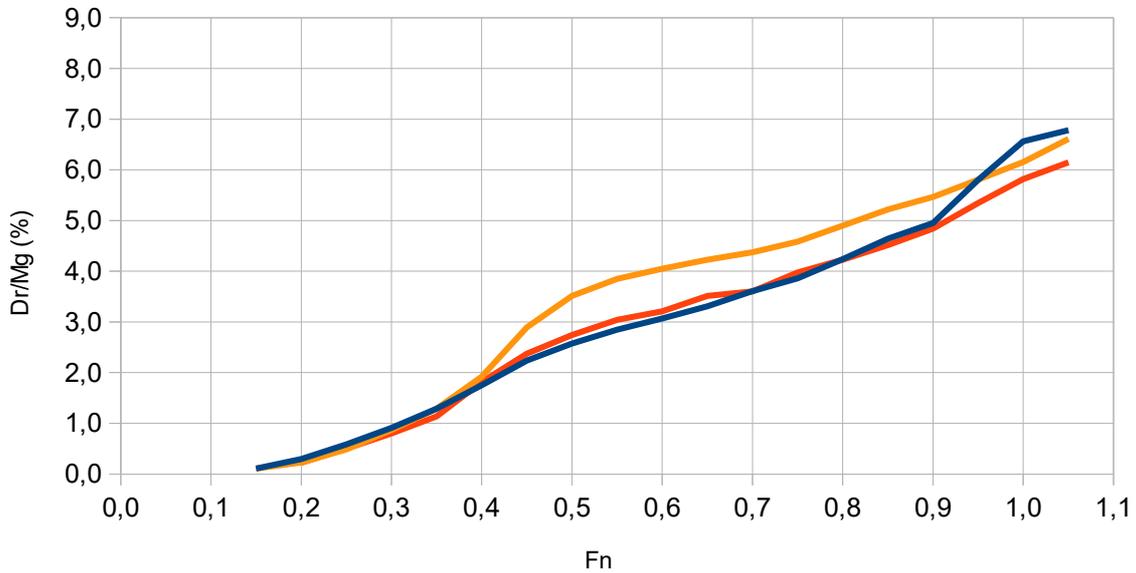

B_{wl}/T_c 2,5 (Blue, from interpolation) 2,0 (Red) 1,5 (Orange, from interpolation)

Bwl/Tc influence at Lwl/Bwl = 11,7

Residuary drag D_r - Monohull C_b 0,397 Lwl/Bwl 11,7

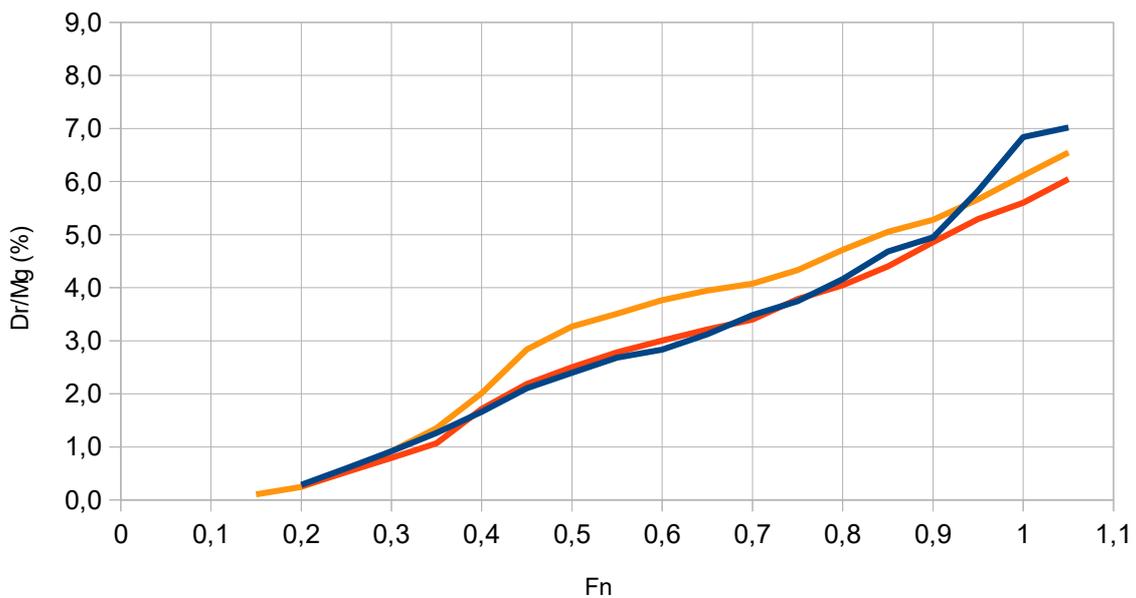

Bwl/Tc 2,5 (Blue) 2,0 (Red, from interpolation) 1,5 (Orange, from interpolation)

Bwl/Tc influence at Lwl/Bwl = 12,8

Residuary drag D_r - Monohull C_b 0,397 Lwl/Bwl 12,8

Bwl/Tc 2,5 (Blue, from interpolation) 2,0 (Red, from interpolation) 1,5 (Orange)

Comments :

- These curves better show the influence of the Bwl/Tc influence, and with consistence : the trends show similarities for each of the 5 cases.

- The conclusions for Froude $< 0,4$ and for $0,95$ to $1,05$ are the same as for the previous comments on Lwl/Bwl influence :
 - For Froude $< 0,15$, D_r is negligible
 - For Froude $0,15$ to $0,40$: no significant difference
 - At Froude $0,95$ to $1,05$ the curves tends to converge to the same drag values.
- For Froude $0,40$ to $0,95$: the graduation of the drag force shows that Bwl/Tc at $1,5$ gives significantly more residuary drag. The drag difference for Bwl/Tc between $2,0$ and $2,5$ is smaller, except at $Lwl/Bwl = 9$ where the $Bwl/Tc = 2,5$ shows a slight advantage.
>>> in this range of Froude ($0,4$ to $0,95$), a correction factor seems relevant to take into account when $Bwl/Tc \neq 2$
